ADF&G TECHNICAL DATA REPORTS

This series of reports is designed to facilitate prompt reporting of data from studies conducted by the Alaska Department of Fish and Game, especially studies which may be of direct and immediate interest to scientists of other agencies.

The primary purpose of these reports is presentation of data. Description of programs and data collection methods is included only to the extent required for interpretation of the data. Analysis is generally limited to that necessary for clarification of data collection methods and interpretation of the basic data. No attempt is made in these reports to present analysis of the data relative to its ultimate or intended use.

Data presented in these reports is intended to be final, however, some revisions may occasionally be necessary. Minor revisions will be made via errata sheets. Major revisions will be made in the form of revised reports.

AGE, SEX, AND SIZE OF YUKON RIVER SALMON CATCH AND ESCAPEMENT, 1982

FOREWORD

This publication is the first in a series of annual catch and escapement reports for the inshore return of Yukon River salmon. The objective of this report is to present the Alaska Department of Fish and Game's (ADF&G) most current estimates of Yukon River salmon abundance, utilization, and age, sex, and size composition. Estimation of these parameters is a prerequisite to studying the population dynamics of Yukon River salmon. Optimum management of the resource requires quantitative estimates of stock-specific production. Unfortunately, the magnitude of total returns is not known and the editors do not attempt to estimate this parameter. Likewise, no attempt has been made to determine the origin of fish caught in mixed stock fisheries. Some of this work is currently in progress and will be reported in future publications. However, catch and escapement data is presented in a manner that will facilitate future investigations of individual species and stock production.

ABSTRACT

Catches and escapements of chinook (*Oncorhynchus tshawytscha*), summer and fall chum (*O. keta*), and coho salmon (*O. kisutch*) for the Yukon River in 1982 are apportioned by age, sex, and size based on the best sample data available. Commercial and subsistence harvest of each species is summarized by age and fishing district. Sonar counts of salmon escapements to selected tributary streams are presented by day, while aerial and foot survey index counts are presented for all other streams surveyed.

INTRODUCTION

The Yukon River drainage supports major runs of chinook salmon (*Oncorhynchus tshawytscha* Walbaum), summer and fall chum salmon (*O. keta* Walbaum), and coho salmon (*O. kisutch* Walbaum). These species contribute to commercial and subsistence fisheries throughout the Yukon River drainage. Both pink salmon (*O. gorbuscha* Walbaum) and sockeye salmon (*O. nerka* Walbaum) are also indigenous to the Yukon River drainage and during some years, pink salmon return in large numbers. Sockeye salmon are only rarely found, and neither species is harvested by commercial or subsistence fishermen to any extent.

Most commercial fishing effort occurs in the lower 232 km (200 mi) of the river. These fisheries harvest mixed species and stocks of salmon bound for spawning areas throughout the Yukon River drainage. Resource management agencies, primarily Alaska Department of Fish and Game (ADF&G) and Environment Canada - Fisheries Service¹, conduct a variety of programs that supply information used to manage the fisheries. These programs include: (1) enumeration of catch in each fishery; (2) sampling major fisheries for age, sex, and size data; (3) indexing the magnitude of major spawning escapements by aerial survey; and (4) sampling major spawning escapements for age, sex, and size data. In some cases, escapements are estimated by visual or hydroacoustic counts, or by tagging studies. Some preliminary work has been done to estimate Yukon River salmon production through identification of major stocks in mixed stock fisheries and allocating these catches to the contributing spawning escapements. The most recent studies have concentrated on chinook salmon (McBride and Marshall 1983), Anvik River summer chum salmon (Buklis 1982), and Yukon and Tanana River fall chum salmon (Buklis 1981). Preliminary studies of total abundance and stock-specific run timing, through analysis of migrating timing of chinook salmon entering the lower Yukon River, have been reported by Mundy (1982) and Clark (1983).

Basic fishery statistics for Yukon River salmon have been presented by several sources. Final commercial catch data for Alaska is annually reported by ADF&G Division of Commercial Fisheries (1982). Total commercial and subsistence catch data (including Canadian catches) is reported in the ADF&G Annual Management Report series (1983). Escapement index and enumeration data are compiled in a computerized data base by Barton (in prep). Age, sex, and size summaries have been annually reported in the ADF&G Arctic-Yukon-Kuskokwim Region Age, Sex, and Size Composition of Salmon Report series (1981) and most recently for the Yukon River by Hamner (1982).

This report presents commercial and subsistence salmon harvest, and enumerated spawning escapements in numbers of fish by age and sex. Indices of relative abundance and age and sex summaries are also presented for other major spawning escapements. Length data is reported by sex and age for each sampled fishery

¹ Fisheries and Oceans, Canada. 122 Industrial Road, Whitehorse, Yukon Territory.

and escapement. No attempt has been made in this report to identify the origin of fish in mixed stock fisheries or to estimate the contribution of any spawning escapement to a fishery. It is hoped that this report will serve as an initial data base for future estimation of these parameters.

METHODS

Study Area Description

The Yukon Area includes all waters of the Yukon River and its tributary streams in Alaska (Figure 1) and the Yukon Territory (Figure 2), and all coastal waters from Canal Point light near Cape Stephens southward to the Naskonat Peninsula. The Alaska portion of the river is divided into six fishing districts as follows: Districts 1, 2, and 3 in the lower Yukon Area; and Districts 4, 5, and 6 in the upper Yukon Area. Commercial fishing occurs throughout the main Yukon River and in the lower 362 km (225 mi) of the Tanana River, however, most of the commercial harvest is taken in Districts 1 and 2. Set and drift gillnets are the legal gear in the lower Yukon, and set gillnets and fishwheels in the upper Yukon. Chinook and fall chum salmon are also commercially harvested in a gillnet fishery near Dawson City, Yukon Territory. Subsistence fishing is allowed throughout the drainage, although most of the effort is concentrated in the main Yukon River. The ADF&G Annual Management Report series (1983) provides a complete description of the Yukon River area and its fisheries.

Abundance Data

Alaskan commercial catch data used in this report was compiled by the Division of Commercial Fisheries for each management district and is based on preliminary computer tabulations of individual fish tickets (ADF&G 1983). These preliminary fish ticket tabulations will not differ significantly from final official tabulations published later by the Alaska Department of Fish and Game. Subsistence catch data was tabulated from catch calendars and personal interviews of subsistence fishermen throughout the drainage (ADF&G 1983). All Yukon Territory catch data was obtained from the Environment Canada - Fisheries Service.

Most of the escapement data presented in this report are peak aerial survey estimates for selected spawning streams (Barton in prep). These estimates are considered indices of relative abundance and do not represent a complete enumeration of season escapement. It is not possible to survey all of the spawning tributaries because of the wide distribution of salmon spawning populations throughout the Yukon River drainage, and personnel and budgetary constraints. However, most of the major spawning populations are surveyed and these indices are taken to represent overall trends in escapement. Total season escapement for several spawning tributaries is estimated by side-scan sonar. They are: (1) East Fork Andreafsky River summer chums, (2) Anvik River summer chums, (3) Melozita River summer chums, and (4) Sheenjek River fall chums. Chinook salmon escapement past the Whitehorse Dam in the Yukon Territory, Canada is visually counted through a fishway. Canadian Fisheries Service conducted a tagging study of chinook and fall chum salmon in the Yukon Territory in 1982, and this data may yield abundance estimates (Mulligan personal communication).

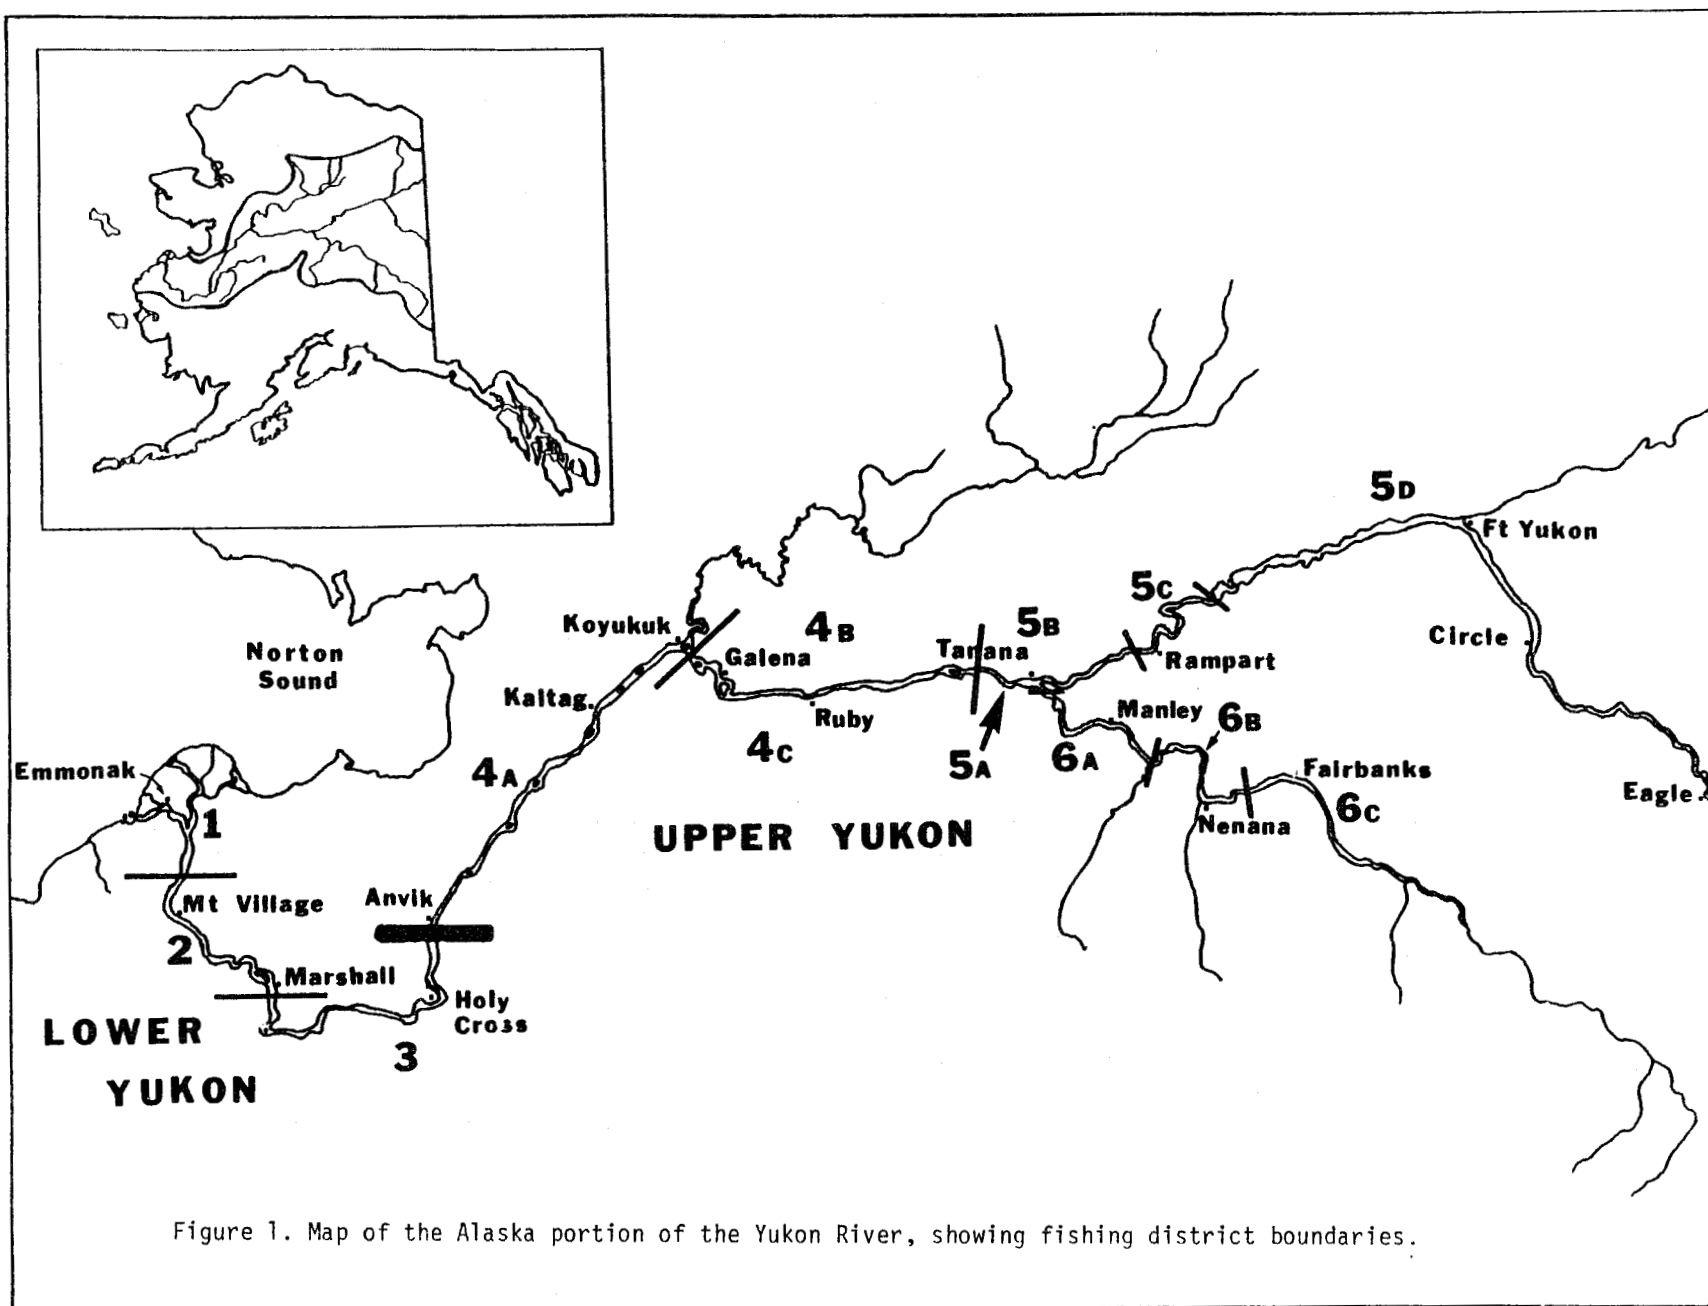

Figure 1. Map of the Alaska portion of the Yukon River, showing fishing district boundaries.

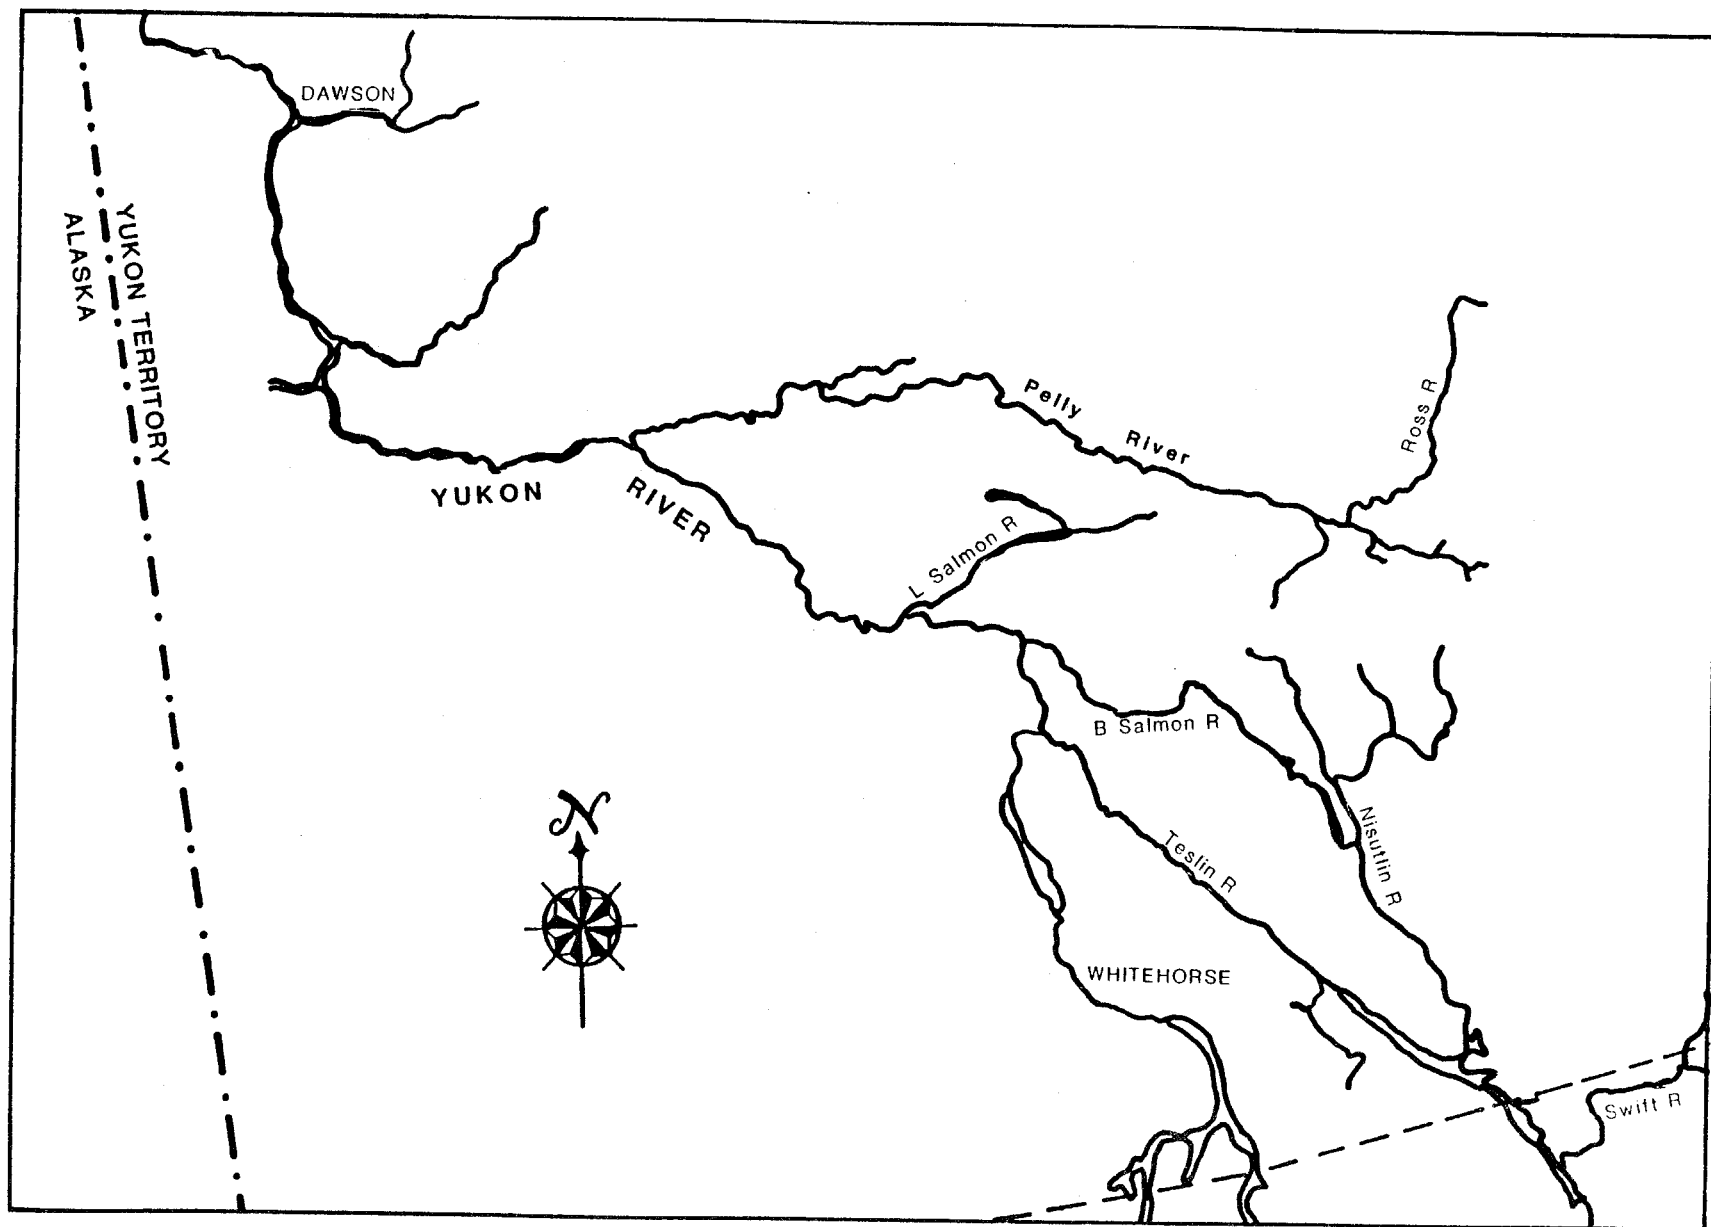

Figure 2. Map of the Canadian portion of the Yukon River.

Age, Sex, and Length Data

Salmon were sampled for scales, sex, and length. Examination of scale samples provided age information of salmon in the catch and escapement. Scales were taken from the left side of the fish approximately two rows above the lateral line and on the diagonal row downward from the posterior insertion of the dorsal fin (INPFC 1963). Scales were mounted on gum cards and impressions made in cellulose acetate (Clutter and Whitesel 1956). Ages are reported in Gilbert-Rich² notations. Sex determination was based on examination of either external morphological features or gonads. Fish length was measured from middle of eye to fork of tail.

An attempt was made to sample fish from the commercial catch for each gear type in each district. However, because of logistic considerations involved in sampling such a widely dispersed fishery, many of the smaller harvests were not sampled. The majority of the commercial catch samples were collected in Districts 1 and 2. Subsistence catches were generally not sampled although some subsistence catch samples were collected in Districts 1 and 6. Chinook, summer chum, fall chum, and coho salmon sample data collected in 1982, but not used to apportion catches, are presented in Appendix Tables 1-4. An attempt was made to sample most of the major chinook and chum salmon spawning populations. Most escapement samples were collected from carcasses, although some live samples were captured by beach seine and gillnet.

Fishery Age and Sex Composition:

Age and sex composition was computed for each fishery sampled and samples were stratified over time (i.e., sample periods) where there were sufficient data. A sample period is defined as the minimum number of samples needed to attain a level of precision, α , of 0.01 and a level of accuracy, d , of 0.05 for determination of the age composition. The number of categories or age groups, k , for each species was defined as the sum of those age groups that comprise at least 90% of the sample plus one (i.e., all of the remaining age groups that comprise the remaining 10% of the sample were pooled into an "other" category for the purpose of calculating k). The parameter, k , was calculated for each species as follows: chinook salmon $k=4$, chum salmon $k=3$, and coho salmon $k=2$. These parameters were then applied to the sample size determination formulas described by Cochran (1977). If there were insufficient samples to attain the above levels of precision and accuracy, the samples were pooled into a single sample period for that fishery. For those fisheries not sampled, age and sex composition was estimated based on samples collected from the nearest fishery in space and time. Catch was then allocated by age and sex.

² Gilbert-Rich formula: The first digit refers to the total age of the fish. The second digit, usually subscripted, refers to the number of years of freshwater residence. Marine age is the difference between these two.

Escapement Age and Sex Composition:

Age and sex composition was determined for each escapement sampled. Samples were collected from carcasses over a short period of time and only an index of relative abundance (aerial survey) was available in most cases. Samples were pooled in a single sample period and no attempt was made to allocate the index escapement estimate by age and sex. For those escapements enumerated by side-scan sonar, total escapement was allocated by age, sex, and size based on carcass, beach seine, or gillnet samples.

Length:

Average length, by sex and age, is reported as a single sample period for each sampled fishery and escapement. Length by age, for both sexes combined, was computed as a weighted average.

RESULTS

Total Utilization

Commercial harvest totaled 123,637 chinook, 614,174 summer chum, 225,027 fall chum, and 37,176 coho salmon in 1982 (Tables 1-7). Chinook, summer chum, and fall chum salmon catches were below the recent 5-year average, while the coho salmon catch was above average. The largest commercial harvest of each salmon species occurred in District 1.

Subsistence harvest totaled 24,114 chinook, 205,065 summer chum, 99,442 fall chum, and 29,813 coho salmon in 1982 (Table 8). The largest chinook and fall chum salmon harvests occurred in District 5, while the largest summer chum salmon harvest occurred in District 4. Most of the coho salmon harvest occurred in Districts 1 and 2.

Age, Sex, and Length Composition

Chinook Salmon:

Age 6₂ chinook made up the majority of the commercial harvest in Districts 1, 2, and 3 at 59%, 63%, and 63%, respectively (Tables 9-13). In Districts 1 and 2, age and sex composition during the first two sample periods (the chinook salmon season) did not change significantly over time. Catches in these districts during the third sample period (the summer chum salmon season) were mostly age 4₂ and 5₂ males (73% and 74%, respectively). District 3 commercial harvest was not sampled, and age and sex samples from the first sample period of District 2 were used to allocate this catch (Table 13).

Commercial gillnet and fishwheel fisheries in Districts 4, 5, and 6 were generally not sampled and the age and sex composition was applied from other sampling areas (Tables 14-21). Age and sex composition of the District 4 fishwheel catch was estimated using commercial catch samples from Galena and test fish catch samples from Stink Creek near Kaltag. Age and sex composition

Table 1. Yukon River District 1 salmon commercial catch by period, 1982^{1 2}.

¹ Allocation based on Dawson commercial catch samples.

of the District 5 gillnet fishery was estimated using commercial catch samples from Dawson, while composition of the District 6 commercial catch is based on District 6 subsistence catch samples.

Age 6₂ chinook predominated gillnet catches in Districts 4 and 5 (46% and 50%, respectively), while collectively, age 4₂ and 5₂ fish predominated the District 4 and District 6 fishwheel catches (85% and 63%, respectively) and the District 6 gillnet catch (66%). The sample sizes were very small and the precision of these estimates is questionable.

The Yukon Territory commercial harvest was primarily 6₂ (50%), 7₂ (23%), and 5₂ (16%) chinook salmon (Tables 21-22).

Subsistence fisheries in Districts 1-5 were not sampled and allocations by gear type, age, and sex are estimated from the appropriate commercial fishery samples (Tables 23-28). The District 6 subsistence harvest was sampled and age 4₂ and 5₂ fish were the predominant age classes (Tables 29-32). Age and sex composition of Yukon Territory subsistence chinook salmon catches were estimated based on Dawson commercial fishery samples (Table 33).

A total of 161,669 chinook salmon were harvested in commercial and subsistence fisheries in all 6 districts and the Yukon Territory combined (Table 34). Age 6₂ (92,608 or 57%) fish were the most abundant age class, followed by age 5₂ (29,672 or 18%), 7₂ (22,697 or 14%), and 4₂ (10,989 or 7%).

Chinook salmon spawn in tributary streams throughout the Yukon River drainage (Figure 3). Aerial survey conditions of spawning escapement during 1982 were generally poor because of inclement weather conditions (Tables 35-37). The only chinook salmon escapement surveyed in the lower portion of the drainage was the Andreafsky River (peak estimate of 1,973 fish). The largest escapements in the middle portion of the drainage were the Salcha, Chena, and Gisasa Rivers (peak estimates of 2,534, 2,073, and 421 fish, respectively). The largest spawning escapements in the Canadian portion of the drainage were the Big Salmon, Nisutlin, Little Salmon, and Wolf Rivers (peak estimates of 1,168, 843, 305, and 225 fish, respectively). A total of 473 chinook salmon passed through the Whitehorse fishway (Table 38). Magnitude of spawning escapements was generally much reduced from levels observed in 1980 and 1981 (ADF&G 1982).

Male fish were more abundant than females in the lower Yukon River escapements (Tables 39-40). Males composed 85% of the Andreafsky River sample and 72% of the Anvik River sample. Age 5₂ was the predominant age class for both rivers (49% and 38%, respectively); followed by age 4₂ (35% and 34%, respectively), and 6₂ (12% and 28%, respectively) fish. All fish had one freshwater check.

Male fish also predominated the middle Yukon River escapements (Tables 41-43). Percentage of males for the Gisasa, Salcha, and Chena Rivers was similar (66%, 62%, and 64%, respectively). Age 6₂ fish predominated the Salcha and Chena River escapements (40% and 38%, respectively), while age 5₂ fish predominated the Gisasa River escapement (44%). Collectively, age 4₂, 5₂, and 6₂ fish composed over 90% of these spawning populations. Only two chinook salmon (both from the Salcha River) had two freshwater annuli (checks) while all other samples were one check.

Female fish were more abundant than males for most Canadian escapements (Tables 44-53). Percentage of females for the Big Salmon, Nisutlin, and Little Salmon Rivers was 67%, 74%, and 59%, respectively. Age 6₂ fish predominated all of these escapements (60%, 77%, and 51%, respectively). Age 7₂ fish contributed a large percentage to the Big Salmon (21%) and Little Salmon River (18%) escapements. Fifty-three chinook salmon with two freshwater checks were found in the Canadian portion of the drainage.

Summer Chum Salmon:

Summer chum salmon commercial catches were sampled in Districts 1 and 2 in the lower Yukon and District 4 in the upper Yukon. Age composition was very similar between District 1 and District 2 catches with age 4₁ contributing 65% and age 5₁ 32% in District 1, while they composed 63% and 33% of the catch in District 2 (Tables 54-57). District 1 samples were separated into three sample periods, with period 1 (6/15-6/22) and period 2 (6/25-7/2) taken during the chinook salmon season and period 3 (7/6-7/13) taken during the summer chum salmon season. Contribution of age 5₁ fish declined, while age 4₁ increased in the catch during these three periods (Table 55). Sex composition did not show any trends through time and averaged 56% male for all samples pooled. District 2 samples were separated into two sample periods, with period 1 (6/17-6/30) taken during the chinook salmon season and period 2 (7/5-7/8) taken during the summer chum salmon season. As in District 1, more age 5₁ fish were taken during the chinook salmon season, while age 4₁ increased during the summer chum season (Table 57). Sex composition was identical for the two periods, averaging 61% male. The District 3 summer chum salmon commercial catch was not sampled, but was allocated to age and sex groups based on District 2 large mesh season samples (Table 58). Most of the District 3 catch was taken with large mesh gear.

Commercial gillnet and fishwheel summer chum salmon catches were sampled in District 4, but not enough samples were collected to allow for separating the data by time period (Tables 59-62B). Gillnet catches were 59% age 4₁ and 36% age 5₁, which is similar to the age composition in the lower Yukon districts. Age composition of commercial fishwheel catches differed between Subdistrict 4A and Subdistricts 4B and 4C. Age 4₁ accounted for 53% and age 5₁ 42% of the Subdistrict 4A catch (Table 62A), while these ages were 77% and 14% of the Subdistrict 4B and 4C catch (Table 62B). District 5 had a commercial catch of only 234 summer chum salmon, no samples were collected, and no attempt was made to allocate this small catch to age and sex groups. District 6 commercial gillnet and fishwheel catches were not sampled, but are presented by age and sex group based on samples collected from other fisheries (Tables 63 and 64). The District 6 commercial gillnet catch of 1,849 summer chum salmon was apportioned based on the District 6 subsistence gillnet sample of 118 fish, and the District 6 commercial fishwheel catch of 21,333 summer chum salmon was apportioned based on the District 4B commercial fishwheel sample of 307 fish. These sample sizes are below the minimum sizes as outlined earlier in this report, and were not collected directly from the catch being apportioned. Therefore, results are of questionable value. This same problem is found in later sections of this report, and indicates the need for increased sampling of some fisheries in the Yukon area.

¹ Allocation based on fishwheel samples from District 4B commercial catch.

The only subsistence fishery sampled was the District 6 gillnet catch. Subsistence catches for Districts 1 through 4 were apportioned based on commercial catch sample data for that district and gear (Tables 65-69). The District 6 subsistence gillnet catch (Tables 70 and 71) was 65% age 4₁ and 23% age 5₁. Sex composition was 64% male. Sex and size composition does not appear to be substantially different than that of commercial gillnet catch samples from the lower Yukon districts. The District 6 subsistence fishwheel catch was not sampled, but is apportioned based on District 4B commercial fishwheel catch samples (Table 72). The District 5 subsistence harvest of 6,931 summer chum salmon was not sampled and is not presented by age and sex group.

A total of 819,231 summer chum salmon was harvested by commercial and subsistence fisheries in the Yukon Area in 1982 (Table 73). The majority of the catch was age 4₁ (61%), followed by age 5₁ (34%), age 6₁ (2%), and age 3₁ (2%) fish.

Summer chum salmon spawn primarily in tributaries of the lower Yukon and Koyukuk Rivers, although small populations occur in a few tributaries in the upper portion of the drainage as well (Figure 4). Aerial survey conditions were generally poor during 1982, and most estimates are only minimal indices of actual spawning escapements (Table 74). Summer chum salmon escapements were considered average in magnitude, based on data from side-scan sonar counters in selected tributaries, but down appreciably from the record levels of 1981. East Fork Andreafsky River escapement was estimated by sonar to be 181,352 summer chum salmon (Table 75). The majority of the fish were age 4₁ (73%), followed by age 5₁ (23%) (Table 76). Sex composition was 65% female. Summer chum salmon escapement to the Anvik River was estimated by sonar to be 444,581 fish (Table 77), and age, sex, and size composition was similar to that of the Andreafsky River. Age 4₁ accounted for 67% of the escapement, age 5₁ 27% (Table 78). Sex composition was 69% female. The sonar count for the Melozitna River was 22,710 summer chum salmon (Table 79). Only 15 samples were collected for age, sex, and size data, and the majority were 4₁ (Table 80). Carcass samples were collected from the Gisasa, Chena, and Salcha Rivers (Tables 81-83). Females outnumbered males and age 4₁ was predominant for each of these three streams, similar to the other escapement sampling.

In summary, age composition was similar between commercial and subsistence harvest and escapement samples of summer chum salmon, while a higher percentage of females were found in the escapement. Each sex was slightly larger (average length) in catch samples than in escapement samples, but the differences do not appear to be significant.

Fall Chum Salmon:

Fall chum salmon commercial catches were sampled in District 1 in the lower Yukon, and at Dawson in the upper Yukon. In addition, test fishing samples were collected in District 4, and were used to apportion commercial catches in Districts 4, 5, and 6.

The District 1 commercial catch was 62% age 4₁, 32% age 5₁, and sex composition was 57% female (Tables 84-85). The District 2 catch of 96,581 (Table 86) and the District 3 catch of 5,815 fall chum salmon (Table 87) were apportioned based on the District 1 sample percentages.

¹ Allocation based on 6 inch gillnet samples from District 1 commercial catch.

No commercial fall chum salmon harvest is taken in Subdistrict 4A. The Subdistrict 4B commercial fishwheel catch is allocated to age and sex groups based on fishwheel test fishing samples from Subdistrict 4B (Table 88A). Age 4₁ was 48% of the catch and age 5₁ 45%. Females accounted for 57% of the catch. The Subdistrict 4C commercial fishwheel catch is apportioned based on Subdistrict 4C fishwheel test fishing samples (Table 88B). Age 4₁ was 66% of the catch, age 5₁ 20%, and age 3₁ 14%. Females accounted for 61% of the total. Tagging studies have shown that fall chum salmon migrating along the north bank of the Yukon River (Subdistrict 4B) are bound for the upper Yukon and Porcupine Rivers, while those on the south bank (Subdistrict 4C) are bound for the Tanana River (Buklis 1981). As in 1981 (Hamner 1982), the north bank stock has a higher percentage of age 5₁ fish and fewer age 3₁ fish than the south bank stock (Tables 88A and 88B). Differences in age composition of the catch in the two subdistricts substantiate the distinct bank orientation of the two stocks first identified by the tagging study.

District 5 and District 6 fall chum salmon commercial fishwheel catches were not sampled. Based on the bank orientation of the two stocks, the Subdistrict 4B fishwheel test fishing sample was used to apportion the District 5 commercial catch (Table 89) and the Subdistrict 4C fishwheel test fishing sample was used for the District 6 commercial catch (Table 90). The commercial gillnet catch in the Dawson area, Yukon Territory was sampled (Tables 91 and 92). Age 5₁ accounted for 57% of the total, age 4₁ 40%. Sex composition was 43% female.

Subsistence harvests in Districts 1, 2, and 3 were apportioned by age and sex based on the District 1 commercial catch sample (Tables 93-95). The District 4 subsistence gillnet catch of 1,615 fall chum salmon was not sampled, and was not apportioned by age and sex because of the lack of any applicable sample data. Subsistence fishwheel catches in District 4 were apportioned based on the test fishing sample from Subdistricts 4B and 4C pooled (Table 96). The District 5 subsistence gillnet catch of 5,372 fall chum salmon was not sampled, and was not separated by age and sex. Although the District 5 subsistence fishwheel catch was not sampled either, the test fishing sample from Subdistrict 4B was applied (Table 97). District 6 gillnet catches were sampled, and age 4₁ was 58% and age 5₁ 32% of the total (Tables 98 and 99). Males accounted for 63% of the catch. The Subdistrict 4C test fishing sample was used to allocate the District 6 subsistence fishwheel catch (Table 100). The Dawson commercial gillnet sample was used for the Dawson subsistence gillnet catch apportionment, since the subsistence harvest was not sampled (Table 101).

A total of 339,094 fall chum salmon was harvested by commercial and subsistence fisheries in the Yukon Area (including Canada) in 1982 (Table 102). The majority of the catch was age 4₁ (59%), followed by age 5₁ (35%), age 3₁ (6%), and age 6₁ (0.3%).

Fall chum salmon spawn in spring fed upwelling areas in streams and sloughs in the upper Yukon River drainage (Figure 5). Aerial survey conditions were generally poor in 1982, although some spawning areas were counted by foot survey with no difficulty (Table 103). Escapements were below average, and record low numbers were observed in the upper Toklat River. Sheenjek River escapement was estimated by sonar to be 29,093 fall chum salmon (Table 104). Drift gillnet samples were 52% age 5₁ and 44% age 4₁ (Table 105). Females accounted for

¹ Allocation based on 5-7/8 inch drift gillnet samples.

62% of the sample. Carcass samples were collected from the Toklat (Table 106) and Delta (Table 107) Rivers. The difference in age composition noted earlier for stocks of the north and south bank of the Yukon River in District 4 are evident between escapement samples in District 5 and District 6. The Sheenjek River sample (District 5) has a higher percentage of age 5₁ fish, while the Toklat and Delta Rivers (District 6) have a higher percentage of age 3₁ and 4₁ fish. These same differences were evident between test fishing samples from the north and south bank of the Yukon River in District 4.

Coho Salmon:

District 1 was the only coho salmon commercial fishery sampled in 1982. Age 4₃ comprised 87% of the catch, age 5₄, 8%, age 3₂, 4%, and age 5₃ about 1% (Tables 108 and 109). The occurrence of coho salmon with two marine checks is unusual for the Yukon River, and was found for only 2 out of the 220 fish sampled. Sex composition was 45% female. The District 2 commercial catch and District 1 and 2 subsistence catches are presented by age and sex based on the District 1 commercial catch sample (Tables 110-112). No other commercial catches in the Yukon Area are apportioned by age and sex because of the lack of any applicable sample data. Most of the District 6 subsistence harvest is taken by fishwheel and no samples were collected. However, an estimated 274 coho salmon were taken for subsistence use by gillnet in District 6, mostly near Fairbanks, and 100 fish were sampled (Tables 113 and 114). Once again ages 4₃ and 5₄ made up the majority of the catch, accounting for 65% and 29% of the total, respectively. Age 3₂ contributed 6%, and no age 5₃ fish were found. Males made up 72% of the catch.

A total of 66,989 coho salmon was taken in commercial and subsistence fisheries in the Yukon Area in 1982 (Table 115). The commercial catch of 37,176 is the second highest on record. Not all catches can be apportioned by age and sex because of the paucity of sample data, but based on the catches that were sampled, the total harvest was 87% age 4₃, 8% age 5₄, 4% age 3₂, and about 1% age 5₃ (Table 115).

Coho salmon spawn in widely scattered tributaries throughout the Yukon River drainage (Figure 6). Major concentrations have been documented in tributaries of the upper Tanana River. Escapements were estimated by foot survey on the Toklat and Delta Rivers, by boat survey on the Delta Clearwater River, and by weir on Julius and Clear Creeks in 1982 (Table 116). Escapements were above average in magnitude in the Tanana River drainage and overall run strength of Yukon River coho salmon was excellent.

ACKNOWLEDGMENTS

The authors would like to thank Henry Yuen for developing the program used to edit and compile the data presented in this report. His help was invaluable. Critical review was provided by Ron Regnart, Bill Arvey, Mike Geiger, and Fred Andersen. Final publication was edited by Gary Finger.

¹ No commercial or subsistence catch samples were collected, therefore District catch is not allocated to age groups.

² Only the subsistence gillnet catch was sufficiently sampled in District 6. No subsistence fishwheel samples and few commercial fishwheel samples were collected. Therefore, neither the commercial nor subsistence catch is allocated to age groups.
